American National Standard
Template Method for Ground Impedance

Secretariat
Acoustical Society of America

Approved 7 July 1999
American National Standards Institute, Inc.

Abstract

This American National Standard describes procedures for obtaining the real and imaginary parts of the specific acoustic impedance of natural ground surfaces outdoors. The Standard uses templates to compare measured sound pressure level differences with a specific set of calculated level differences. The impedance values are obtained from a model based on best fit of measured and calculated level differences. The Standard may also be used to obtain the impedance of porous sound absorbing material.

AMERICAN NATIONAL STANDARDS ON ACOUSTICS

The Acoustical Society of America (ASA) provides the Secretariat for Accredited Standards Committees S1 on Acoustics, S2 on Mechanical Vibration and Shock, S3 on Bioacoustics, and S12 on Noise. These committees have wide representation from the technical community (manufacturers, consumers, and general-interest representatives). The standards are published by the Acoustical Society of America through the American Institute of Physics as American National Standards after approval by their respective standards committees and the American National Standards Institute.

These standards are developed and published as a public service to provide standards useful to the public, industry, and consumers, and to Federal, State, and local governments.

Each of the Accredited Standards Committees (operating in accordance with procedures approved by ANSI) is responsible for developing, voting upon, and maintaining or revising its own standards. The ASA Standards Secretariat administers committee organization and activity, and provides liaison between the Accredited Standards Committees and ANSI. After the Standards have been produced and adopted by the Accredited Standards Committees, and approved as American National Standards by ANSI, the ASA Standards Secretariat arranges for their publication and distribution.

An American National Standard implies a consensus of those substantially concerned with its scope and provisions. Consensus is established when, in the judgment of the ANSI Board of Standards Review, substantial agreement has been reached by directly and materially affected interests. Substantial agreement means much more than a simple majority, but not necessarily unanimity. Consensus requires that all views and objections be considered and that a concerted effort be made toward their resolution.

The use of American National Standards is completely voluntary. Their existence does not in any respect preclude anyone, whether he or she has approved the standards or not, from manufacturing, marketing, purchasing, or using products, processes, or procedures not conforming to the standards.

NOTICE: This American National Standard may be revised or withdrawn at any time. The procedures of the American National Standards Institute require that action be taken periodically to reaffirm, revise, or withdraw this Standard.

Foreword

[This Foreword is for information only and is not a part of *American National Standard Template Method for Ground Impedance*, ANSI S1.18-1999.]

This Standard was developed under the jurisdiction of Accredited Standards Committee S1, Acoustics, using the American National Standards Institute (ANSI) Accredited Standards Committee Procedure. The Acoustical Society of America provides the Secretariat for Accredited Standards Committee S1, Acoustics.

Accredited Standards Committee S1, Acoustics, under whose jurisdiction this Standard was developed, had the following scope:

Standards, specifications, methods of measurement and test, and terminology in the fields of physical acoustics including architectural acoustics, electro-acoustics, sonics and ultrasonics, and underwater sound, but excluding those aspects which pertain to biological safety, tolerance, and comfort.

At the time this Standard was submitted to Accredited Standards Committee S1, Acoustics, for approval, the membership was as follows:

J. P. Seiler, *Chairman*
G. S. K. Wong, *Vice Chair*
A. Brenig, *Secretary*

Acoustical Society of America	J. P. Seiler G. S. K. Wong (<i>Alt.</i>)
Air-Conditioning and Refrigeration Institute	R. Comparin S. Sanders (<i>Alt.</i>)
American Industrial Hygiene Association	L. H. Royster J. F. Meagher (<i>Alt.</i>)
Audio Engineering Society	L. W. Sepmeyer M. R. Chial (<i>Alt.</i>)
Bruel & Kjaer Instruments	M. Alexander J. Chou (<i>Alt.</i>)
Information Technology Industry Council	R. Lotz J. Godfrey (<i>Alt.</i>)
Larson-Davis Laboratories	L. Davis J. H. Carey (<i>Alt.</i>)
Lucent Technologies	L. A. Marcus J. C. Baumhauer (<i>Alt.</i>)
National Council of Acoustical Consultants	G. Winzer
National Institute of Standards and Technology	V. Nedzelnitsky D. J. Evans (<i>Alt.</i>)
Sonetronics, Inc.	R. T. Linderoth
U. S. Army Aeromedical Research Laboratory	(vacant)
U. S. Army Human Research & Engineering Directorate (HRED)	J. Kalb T. Letowski (<i>Alt.</i>)
U. S. Department of the Air Force	R. McKinley
U. S. Army Construction Engineering Research Laboratories (USA-CERL)	P. D. Schomer

Individual experts of Accredited Standards Committee S1, Acoustics, were:

J. R. Bareham
S. L. Ehrlich
K. M. Eldred
W. J. Galloway

D. L. Johnson
T. J. Kuemmel
W. W. Lang
A. H. Marsh

H. E. von Gierke
G. S. K. Wong
R. W. Young

Working Group S1/WG20, Ground Impedance, which assisted Accredited Standards Committee S1, Acoustics, in the development of this Standard, had the following membership:

G. A. Daigle, *Chair*

K. Attenborough
Y.-L. Li
J. Noble
J. M. Sabatier

M. R. Stinson
L. C. Sutherland
M. J. White
A. J. Zuckerwar

Suggestions for improvements of this Standard will be welcomed. Send suggestions for improvement to Accredited Standards Committee S1, Acoustics, in care of the ASA Standards Secretariat, 120 Wall Street, 32nd Floor, New York, NY 10005-3993, USA.

American National Standard

Template Method for Ground Impedance

0 Introduction

This Standard is concerned with obtaining ground impedance from simple *in situ* measurements. It is possible to perform the measurements with simple instrumentation such as a hand-held sound level meter. The Standard adopts the use of templates to compare sound pressure level differences measured above ground surfaces with calculated level differences. The real and imaginary parts of the ground impedance are obtained by best fit.

The experimental techniques to measure impedance include the use of an impedance tube, free field techniques that measure the sound pressure levels above a surface, and direct sound pressure–volume velocity measurements.

The impedance tube is in common use to measure the impedance of porous materials. It has the advantage of a straightforward theoretical framework that allows direct determination of both the real and imaginary parts of the impedance. However, its application in the field to obtain ground impedance suffers from two major disadvantages. First, it requires an accurate measurement of the distance from the first interference minimum to an ill-defined test surface and, second, it is invasive. This Standard does not recommend the use of an impedance tube for the measurement of ground impedance.

Free-field techniques include a multitude of variations based on the type of excitation, angle of incidence, number of microphones, and parameter evaluation. All enjoy the advantage that the measurement is performed on the ground in its natural condition. However, due to the spherical wavefronts, the theoretical framework is mathematically intricate, making the direct extraction of both the real and imaginary parts of the impedance difficult. Research on this point is ongoing. The use of an impedance model overcomes some of the difficulties. This Standard uses three well-established ground impedance models to calculate a set of templates for free field level differences. The use of a user-defined model is not precluded. The real

and imaginary parts of the impedance are obtained by best fit to measured level differences.

This Standard does not consider the direct measurement of sound pressure and volume velocity.

1 Scope

This Standard describes recommended procedures to characterize, and the instrumentation to measure, the acoustic properties of a variety of ground surfaces. Although this Standard is intended primarily for outdoor measurements, indoor measurement of intact portions of a ground surface, such as sod, is also allowed.

The use of the Standard to characterize the properties of porous materials in general from a free field measurement is allowed.

The Standard yields values of the real and imaginary parts of the specific acoustic impedance of ground surfaces in the frequency range between 250 and 4000 Hz for outdoor sound propagation predictions. The Standard uses the variation of the ground attenuation with ground properties to obtain the impedance. Outside the frequency range of interest, the method is not expected to yield accurate results.

2 Purpose

The basic purpose of this Standard is to establish uniform procedures for obtaining the real and imaginary parts of the specific acoustic impedance of ground surfaces outdoors.

3 Application

This Standard may be used to obtain the impedance of commonly occurring ground surfaces. The Standard offers a choice between a simple one-parameter model and a more precise two-parameter model to calculate templates suitable for routine environmental purposes. In cases where more precision is required, guidance is given to use a four-parameter model and its simplification to calculate alternative templates.

The template method is not applicable to complex ground structures such as multiple-layered material. The template method is expected to yield less accuracy with snow-covered ground.
