Foreword

Approval of an American National Standard requires verification by ANSI that the requirements for due process, consensus, and other criteria for approval have been met by the standards developer.

Consensus is established when, in the judgment of the ANSI Board of Standards Review, substantial agreement has been reached by directly and materially affected interests. Substantial agreement means much more than a simple majority, but not necessarily unanimity. Consensus requires that all views and objections be considered, and that a concerted effort be made toward their resolution.

The use of American National Standards is completely voluntary; their existence does not in any respect preclude anyone, whether he has approved the standards or not from manufacturing, marketing, purchasing, or using products, processes, or procedures not conforming to the standards.

The American National Standards Institute does not develop standards and will in no circumstances give an interpretation of any American National Standard. Moreover, no person shall have the right or authority to issue an interpretation of an American National Standard in the name of the American National Standards Institute. Requests for interpretation should be addressed to the secretariat or sponsor whose name appears on the title page of this standard.

CAUTION NOTICE: This American National Standard may be revised or withdrawn at any time. The procedures of the American National Standards Institute require that action be taken to reaffirm, revise, or withdraw this standard no later than five years from the date of approval.

ANSI X9.73-2010 (R2017)

Introduction

Financial business practices have changed with the introduction of computer and network-based technologies. Increased reliance on electronic transactions has heightened the need to manage the security of information and communications technology. Huge amounts in funds and securities are transferred daily by electronic communication mechanisms controlled by security practices based on business policies.

The high value or sheer volume of such transactions within an open environment exposes the financial community to the risk of potentially severe consequences from accidental or deliberate disclosure, alteration, substitution, or destruction of data. This risk is compounded by interconnected networks, and the increased number and sophistication of malicious adversaries. And when financial transactions involve systemically important payment systems, these consequences may adversely affect national and global financial markets.

This Standard defines a cryptographic message syntax which can be used to protect financial transactions and other information from the threats described above. The syntax is easily extensible in design to allow the use of any cryptographic algorithm defined in current or future standards appropriate for use by the financial services. The cryptographic syntax is suitable for the protection of the identity and rights management information critical for secure access control.

The syntax provides support for data confidentiality, data integrity, data origin authentication, and non-repudiation services needed to provide strong, mutual authentication. These services can be applied to prevent innovative types of fraud such as 'phishing' that are aimed at identity impersonation and theft, and which threaten the interests of financial institutions and their customers, the merchants, consumers and other actors of commerce.

Flexibility of key management techniques is provided through support for a variety of key establishment mechanisms, including key exchange, key agreement, password-based encryption and constructive key management. These techniques can be employed to mitigate risks, and to help financial institutions meet the legal and regulatory requirements of protecting sensitive business information, and the personal information of their customers and employees.

Use of this widely deployed syntax will lead to quick market acceptance in the financial community, lower costs due to economy of scale, and interoperability with a large number of existing standards and applications.

Suggestions for the improvement or revision of this Standard are welcome. They should be sent to the X9 Committee Secretariat, Accredited Standards Committee X9, Inc., Financial Industry Standards, 275 West Street, Suite 107, Annapolis, MD 21401 USA.

This Standard was processed and approved for submittal to ANSI by the Accredited Standards Committee on Financial Services, X9. Committee approval of the Standard does not necessarily imply that all the committee members voted for its approval.

At the time this standard was approved, the X9 committee had the following members:

Roy DeCicco, X9 Chairman
Vincent DeSantis, X9 Vice-Chairman
Steve Stevens, Executive Director
Janet Busch, Program Manager

Under ASC X9, Inc. procedures, a working group may be established to address specific segments of work under the ASC X9 Committee or one of its subcommittees. A working group exists only to develop standard(s) or guideline(s) in a specific area and is then disbanded. The individual experts are listed with their affiliated organizations. However, this does not imply that the organization has approved the content of the standard or guideline. (Note: Per X9 policy, company names of non-member participants are listed only if, at the time of publication, the X9 Secretariat received an original signed release permitting such company names to appear in print.)

At the time this standard was approved, the X9F4 Cryptographic Protocol and Application Security working group which developed this standard had the following active members:

Jeff Stapleton, X9F4 Chair
Sandra Lambert, X9F4 Vice Chair
Phillip H. Griffin, X9.73 Editor

This document cancels and replaces previous versions of X9.73 and X9.96 in whole.

This document merges together into a single national standard previous versions of the X9.73 and X9.96 standards, and provides a common, abstract, cryptographic messaging schema that supports both a compact binary and a verbose textual format of its messages.

Cryptographic Message Syntax - ASN.1 and XML

1 Scope

This Standard specifies a cryptographic syntax scheme which can be used to protect financial transactions, files and other messages from unauthorized disclosure and modification. The cryptographic syntax scheme is based on an abstract Cryptographic Message Syntax (CMS) schema whose concrete values can be represented using either a compact, efficient, binary encoding, or as a flexible, human-readable, XML markup format. The syntax scheme has the following characteristics:

- 1) Protected messages are represented as XML markup using the Canonical XML Encoding Rules (cXER), or represented in a binary format that is backward compatible with existing deployed systems that rely on cryptographic message syntax, using the Basic Encoding Rules (BER) or the canonical subset of BER, the Distinguished Encoding Rules (DER).
- 2) Messages are protected independently. There is no cryptographic sequencing (e.g., cipher block chaining) between messages. There need not be any realtime connection between the sender and recipient of the message. This makes the syntax suitable for use over store-and-forward systems, e.g. Automated Clearing House (ACH) or Society for Worldwide Interbank Financial Telecommunication (SWIFT).
- 3) Standard attributes are defined using an extensible design to allow any organization with a need to define additional attributes for any purpose. Attributes are defined that allow Security Assertion Markup Language (SAML) and Extensible Markup Language (XML) Key Management Specification (XKMS) content to be carried in each of the cryptographic types defined in X9.73.
- 4) The syntax is cryptographic algorithm independent and extensible. It supports provision of data confidentiality, data integrity, data origin authentication, and non-repudiation services. Any algorithm may be used for message encryption, digital signature, MAC, and key management. A variety of key management techniques are supported, including key exchange, key agreement, password-based encryption and constructive key management.
- 5) Selective field protection can be provided in two ways. First by combining multiple instances of this syntax into a composite message. And second by using identifier and type markup tag names to select message components to be protected in a single message. This approach allows reusable message components to be moved between documents without affecting the validity of the signature.
- 6) Precise message encoding and detailed cryptographic processing requirements of binary and XML markup message representations are provided.

Simple Object Application Protocol (SOAP) message extensions are defined for each of the cryptographic types defined in X9.73 to enable protection of financial services information in Web Services environments.
