Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

The procedures used to develop this document and those intended for its further maintenance are described in the ISO/IEC Directives, Part 1. In particular, the different approval criteria needed for the different types of ISO documents should be noted. This document was drafted in accordance with the editorial rules of the ISO/IEC Directives, Part 2 (see www.iso.org/directives).

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights. Details of any patent rights identified during the development of the document will be in the Introduction and/or on the ISO list of patent declarations received (see www.iso.org/patents).

Any trade name used in this document is information given for the convenience of users and does not constitute an endorsement.

For an explanation of the voluntary nature of standards, the meaning of ISO specific terms and expressions related to conformity assessment, as well as information about ISO's adherence to the World Trade Organization (WTO) principles in the Technical Barriers to Trade (TBT), see www.iso.org/iso/foreword.html.

This document was prepared by Technical Committee ISO/TC 268, *Sustainable cities and communities*, Subcommittee SC 1, *Smart community infrastructures*.

Any feedback or questions on this document should be directed to the user's national standards body. A complete listing of these bodies can be found at www.iso.org/members.html.

Introduction

Energy savings is a priority issue for all cities. ISO 37154, and especially ISO 37161, has addressed how, where and in what situations energy consumed in transportation services can be saved.

Rail services are indispensable as one of the most efficient means to convey people, delivery items and freight within cities, between cities and in a large city zone. Rail services are comprised of many service and technical aspects. To save energy in rail services, there are many options to review for improving energy efficiency. Energy savings by slowing the speed of the train and still achieving minimum service schedules is a method that is frequently employed. This method of operation is applicable to other transportation services or modes that are based on scheduling. Energy saving by modifying speed profiles offers great energy savings when widely applied to all transportation services.

The principle of this method is rather simple. All trains, buses, trucks and ferries typically run on a service line or sailing route at the maximum speed technically allowed. Reducing the running speed will reduce the energy consumption. Commonly, all transportation modes, passengers and freight, are scheduled to include standing-by time to provide passengers and freight shippers with convenient service schedules, providing good connections and avoiding odd time for pickup and delivery. Service schedules can be designated so that when passing another service at a station with more tracks or lanes on a single-track line or traffic road, or at a wider point on a narrow sailing route, a train, bus, truck or ferry should come to the station or point by the time designated. If the designated arriving time is set later than the expected arrival time at a maximum speed, the train or other transportation mode can run slower. Overall, this will lead to a reduction in the amount of energy to be consumed.

Slow running avoids high acceleration and deceleration, compared to when running at a higher speed. Passenger-friendly driving will additionally be realized when operating in this energy saving method. From an environmental standpoint, slow running will contribute to a reduction in carbon monoxide emission, hydrocarbons, nitrogen oxides, sulphur oxides, lead and aromatic compounds, if services by engine-driven vehicles.

This document describes how to save energy in scheduled transportation services by modifying speed profiles.

In the development of this document, ISO Guide 82 has been taken into account in addressing sustainability issues.
