## Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

The procedures used to develop this document and those intended for its further maintenance are described in the ISO/IEC Directives, Part 1. In particular, the different approval criteria needed for the different types of ISO documents should be noted. This document was drafted in accordance with the editorial rules of the ISO/IEC Directives, Part 2 (see [www.iso.org/directives](http://www.iso.org/directives)).

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights. Details of any patent rights identified during the development of the document will be in the Introduction and/or on the ISO list of patent declarations received (see [www.iso.org/patents](http://www.iso.org/patents)).

Any trade name used in this document is information given for the convenience of users and does not constitute an endorsement.

For an explanation of the voluntary nature of standards, the meaning of ISO specific terms and expressions related to conformity assessment, as well as information about ISO's adherence to the World Trade Organization (WTO) principles in the Technical Barriers to Trade (TBT) see [www.iso.org/iso/foreword.html](http://www.iso.org/iso/foreword.html).

This document was prepared by Technical Committee ISO/TC 229, *Nanotechnologies*.

Any feedback or questions on this document should be directed to the user's national standards body. A complete listing of these bodies can be found at [www.iso.org/members.html](http://www.iso.org/members.html).

## Introduction

There is an interest in determining the concentration of nano-objects and their aggregates and agglomerates (NOAA) in environmental matrices. Manufactured nanomaterials (NM) enter the environment via release from the manufacturing process and its waste streams, as well as via the use of commercial products and their recycle and disposal streams. Such measurement efforts require an understanding of the occurrence of natural materials that can interfere with the analysis or skew the results, knowledge of how the environment can interact with NM, and insights that require unique collection and analytical techniques specific to the composition of the particle. This document provides a review of published studies that report levels of NOAA in the environment and aspects of collection and sample preparation. The reader is also directed to the Further Reading section of this document for information regarding ISO guidance on sampling of air, water, and sediment, as well as a matrix of measurement techniques.

Not all manufactured NM are discussed here because there might not yet be published studies that examined them in the environment. On the other hand, collection methods and pre-analytical procedures might be similar for some or all NOAA in a given environmental matrix. Furthermore, NOAA isolated from the environment can be characterized using the same instruments and analytical techniques used for pristine NOAA. Thus, the lack of published studies does not preclude the ability to collect a specific NM from any environmental matrix and measure the NOAA present.

Although it is recognized that biota (i.e. living organisms) also can interact with NM by sequestering and/or transforming them, analysis of biota is intentionally excluded so that the scope of this Document does not become too broad. However, the impact of biota should not be overlooked. Such considerations could be part of a subsequent Technical Report.

Furthermore, when NM are used for environmental remediation, and there is interest in measuring residual levels of remediating NM after the environmental medium has been processed. It is anticipated that the considerations described here would be applicable to those investigations.

The audience for this document is expected to be scientists from the regulatory, academic, or industrial communities who wish to answer the question of how much manufactured NM is present in a specific environmental medium. The results could be used for environmental stewardship, for risk assessment, or to calibrate modelled exposure estimates, although these applications are not discussed here.

**NOTE** The term NM refers to the identity of the nanomaterial, whereas NOAA is a more inclusive term encompassing NM and aggregates that are the focus of the analyses described here.
